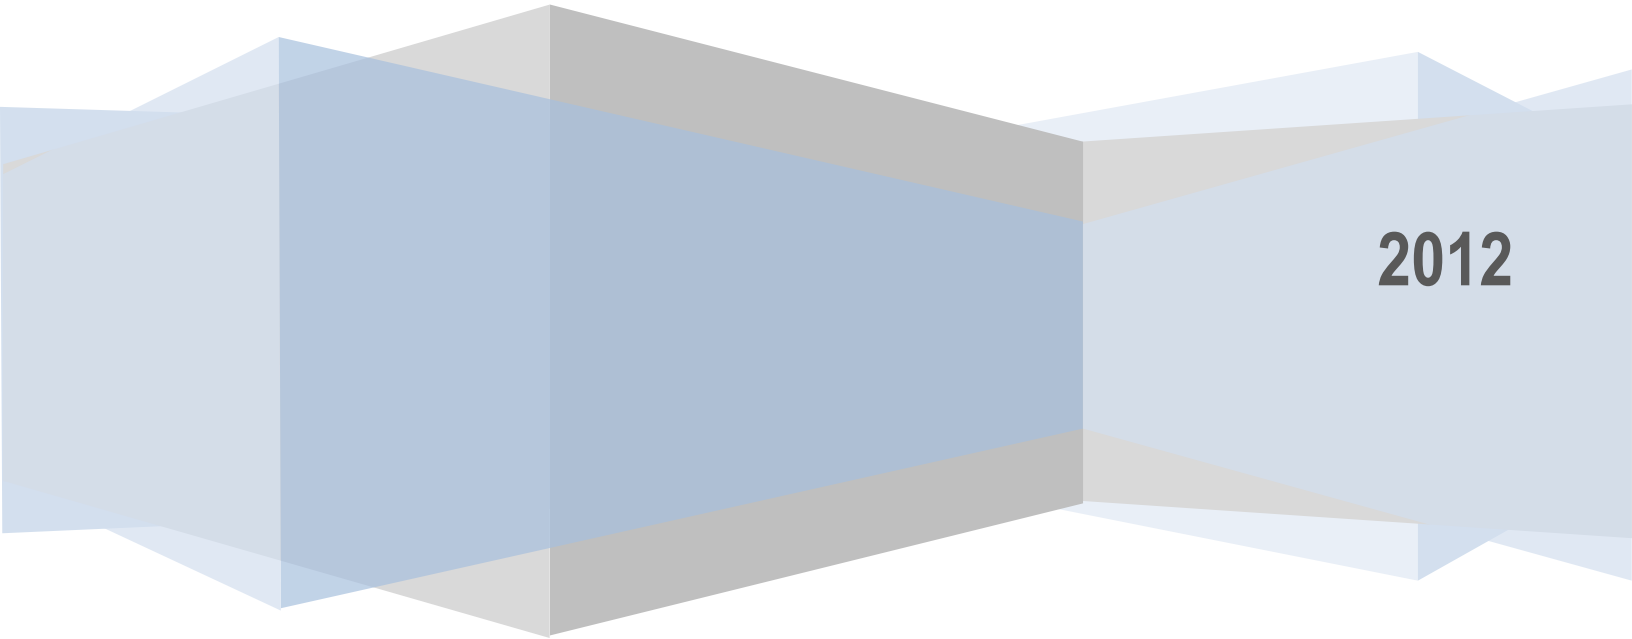
Digital Motor Control

Software Library:
F2805x Drivers



2012

Contents

Introduction

The digital motor control library is composed of C functions (or macros) developed for C2000 motor control users. These modules are represented as modular blocks in C2000 literature in order to explain system-level block diagrams clearly by means of software modularity. The DMC library modules cover nearly all of the target-independent mathematical macros and target-specific peripheral configuration macros, which are essential for motor control. These modules can be classified as:

Transformation and Observer Modules	Clarke, Park, Phase Voltage Calculation, Sliding Mode Observer, BEMF Commutation, Direct Flux Estimator, Speed Calculators and Estimators, Position Calculators and Estimators etc.
Signal Generators and Control Modules	PID, Commutation Trigger Generator, V/f Controller, Impulse Generator, Mod 6 Counter, Slew Rate Controllers, Saw-tooth & Ramp generators, Space Vector Generators etc.
Peripheral Drivers	PWM abstraction for multiple topologies and techniques, ADC Drivers, Hall Sensor Driver, QEP Driver, CAP Driver etc.
Real-Time Debugging Modules	DLOG module for CCS graph window utility, PWMDAC module for monitoring the control variables through oscilloscope

In the DMC library, each module is separately documented with source code, use, and background technical theory. All DMC modules allow users to quickly build, or customize their own systems. The library supports three principal motor types (induction motor, BLDC and PM motors) but is not limited to these motors.

The DMC library components have been used by TI to provide system-level motor control examples. In the motor control code, all DMC library modules are initialized according to the system specific parameters, and the modules are inter-connected to each other. At run-time the modules are called in order. Each motor control system is built using an incremental build approach, which allows some sections of the code to be built at a time, so that the developer can verify each section of the application one step at a time. This is critical in real-time control applications, where so many different variables can affect the system, and where many different motor parameters need to be tuned.

Description This module allows the user to configure analog-to-digital conversion (ADC) channels. The conversions are triggered on end of conversion (EOC) which is set to 4th conversion by default. In DMC projects, the converted results represent load currents and DC-bus voltage but not limited to these.

Module Properties

Type: Target Dependent, Application Independent

Target Devices: 28x Fixed Point

C Version File Names: f2805xileg_vdc.h (for x2805x)

IQmath library files for C: N/A

C Interface

Module Usage

Instantiation
There is no instantiation for ADC configuration.

Initialization

```
// Default ADC initialization
int ChSel[16] = Default_ch_sel;
int TrigSel[16] = Default_trig_sel;
 int ACQPS[16] = Default_ACQPS;
```

Where:

ChSel [ ] stores which ADC pin is used for conversion when a Start of Conversion (SOC) trigger is received for the respective channel

TrigSel [ ] stores what trigger input starts the conversion of the respective channel

ACQPS [ ] stores the acquisition window size used for the respective channel

Invoking the computation macro

```
ChSel[0] = x;
ChSel[1] = y;
ChSel[2] = z;

ADC_MACRO_INIT(ChSel,TrigSel,ACQPS);
```

Example

The following pseudo code provides the information about the module usage.

```
main()
{
        ChSel[1] = 1;     // ChSelect: ADC A1-> Phase A Current
        ChSel[2] = 9;     // ChSelect: ADC B1-> Phase B Current
        ChSel[3] = 3;     // ChSelect: ADC A3-> Phase C Current
        ChSel[7] = 10;   // ChSelect: ADC B2-> DC Bus  Voltage

        ADC_MACRO_INIT(ChSel,TrigSel,ACQPS)          // Call init macro for ADC INIT
}

void interrupt periodic_interrupt_isr()
{
clarke1.As = _IQmpy2(_IQ12toIQ(AdcResult.ADCRESULT1) - offsetA); // Phase A curr.
clarke1.Bs = _IQmpy2(_IQ12toIQ(AdcResult.ADCRESULT2) - offsetB); // Phase B curr.
volt1.DcBusVolt = _IQ12toIQ(AdcResult.ADCRESULT7);          // DC Bus voltage meas.
}
```

Description

This module generates the 6 switching states of a 3-ph power inverter used to drive a 3-ph BLDC motor. These switching states are determined by the input variable *CmtnPointer*. The module also controls the PWM duty cycle by calculating appropriate values for the compare registers. The duty cycle values for the PWM outputs are determined by the input *DutyFunc*.

Object Definition

The structure of PWMGEN object is defined by following structure definition

```
typedef struct {  Uint16 CmtnPointer;  // Input: Commutation (or switching) state pointer input (Q0)
                  int16 MfuncPeriod;    // Input: Duty ratio of the PWM outputs (Q15)
                  Uint16 PeriodMax;    // Parameter: Maximum period (Q0)
                  int16 DutyFunc;       // Input: PWM period modulation input (Q15)
                  Uint16 PwmActive;   // Parameter: 0 = active low, 1 = active high (0 or 1)
                } PWMGEN;
```

Item	Name	Description	Format	Range(Hex)
Inputs	CmtnPointer	Commutation (or switching) state pointer input	Q0	0 - 5
	MfuncPeriod	Duty ratio of the PWM outputs	Q15	8000-7FFF
	DutyFunc	PWM period modulation input	Q15	8000-7FFF
Outputs	PWMx	Output signals from the 6 PWM pins	N/A	0-3.3 V
PWMGEN parameter	PeriodMax	PWM Period in CPU clock cycles	Q0	8000-7FFF
	PwmActive	0 = PWM active low 1 = PWM active high	Q0	0 or 1

Special Constants and Data types

PWMGEN

The module definition is created as a data type. This makes it convenient to instance an interface to the PWMGEN driver. To create multiple instances of the module simply declare variables of type PWMGEN.

PWMGEN_DEFAULTS

Structure symbolic constant used to initialize PWMGEN module. This provides the initial values to the terminal variables as well as method pointers.

This default definition of the object implements two methods – the initialization and the runtime compute macro for PWMGEN generation. This is implemented by means of a macro pointer, and the initializer sets this to BLDCPWM_INIT_MACRO and BLDCPWM_MACRO macros for F280x. The argument to this macro is the address of the PWMGEN object.

Module Usage

Instantiation
The following example instances one PWMGEN object
PWMGEN pwm1;

Initialization
To Instance pre-initialized objects
PWMGEN pwm1 = PWMGEN_DEFAULTS;

Invoking the computation macro
BLDCPWM_INIT_MACRO (pwm1);
BLDCPWM_MACRO (pwm1);

Example

The following pseudo code provides the information about the module usage.

```
main()
{

        pwm1.PeriodMax = 7500;  // PWM frequency = 20 kHz, clock = 150 MHz
         BLDCPWM_INIT_MACRO(pwm1);                  // Call init macro for pwm1

}

void interrupt periodic_interrupt_isr()
{

         pwm1.CmtnPointer = (int) (CmtnPointer1);          // CmtnPointer1 is in Q0
         pwm1.DutyFunc = (int) _IQtoIQ15(DutyFunc1);      // DutyFunc1 is in GLOBAL_Q
         BLDCPWM_MACRO(pwm1);                       // Call update macro for pwm1

}
```

Technical Background

Figure 1 shows the 3-phase power inverter topology used to drive a 3-phase BLDC motor. In this arrangement, the motor and inverter operation is characterized by a *two phases ON* operation. This means that two of the three phases are always energized, while the third phase is turned off. This is achieved by controlling the inverter switches in a periodic 6 switching or commutation states. The bold arrows on the wires in Figure 1 indicate the current flowing through two motor stator phases during one of these commutation states. The direction of current flowing into the motor terminal is considered as positive, while the current flowing out of the motor terminal is considered as negative. Therefore, in Figure 1, Ia is positive, Ib is negative and Ic is 0.

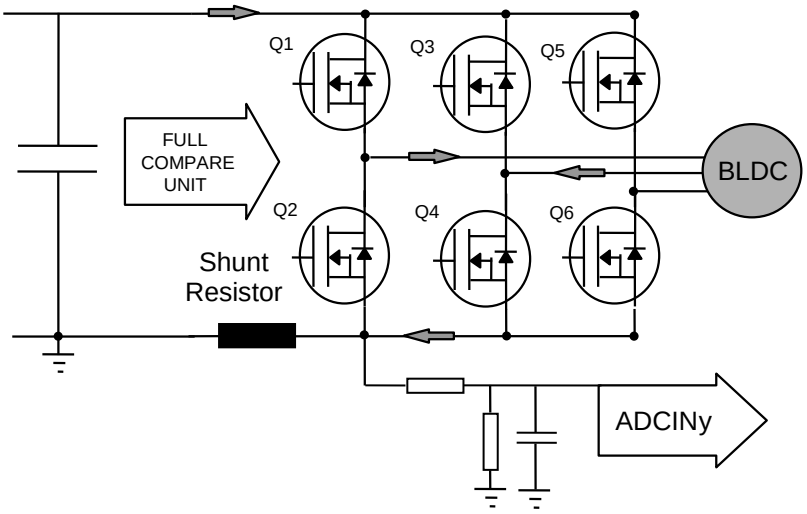

Figure 1: Three Phase Power Inverter for a BLDC Motor Drive

In this control scheme, torque production follows the principle that current should flow in only two of the three phases at a time and that there should be no torque production in the region of Back EMF zero crossings. Figure 2 depicts the phase current and Back EMF waveforms for a BLDC motor during the *two phases ON* operation. All the 6 switching states of the inverter in Figure 1 are indicated in Figure 2 by S1 through S6. As evident from Figure 2, during each state only 2 of the 6 switches are active, while the remaining 4 switches are turned OFF. Again, between the 2 active switches in each state, the odd numbered switch (Q1or Q3 or Q5) are controlled with PWM signal while the even numbered switch (Q2 or Q4 or Q6) is turned fully ON. This results in motor current flowing through only two of the three phases at a time. For example in state S1, Ia is positive, Ib is negative and Ic is 0. This is achieved by driving Q1 with PWM signals and turning Q4 fully ON. This state occurs when the value in the commutation state pointer variable, *CmtnPointer*, is 0. Table 1 summarizes the state of the inverter switches.

and the corresponding values of the related peripheral register, the commutation pointer and the motor phase currents.

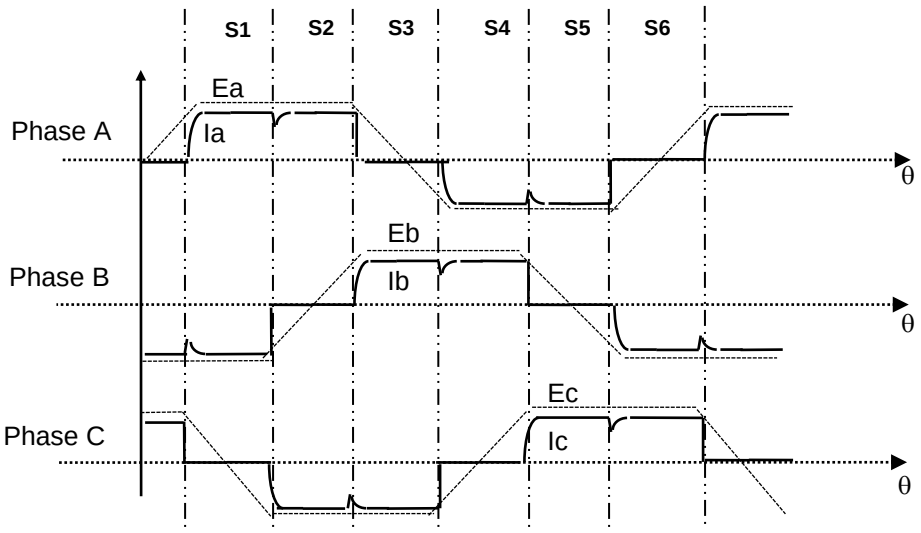

Figure 2: Phase Current and Back EMF Waveforms in 3-ph BLDC Motor control

State	CmtnPointer	ACTR	Q1	Q2	Q3	Q4	Q5	Q6	Ia	Ib	Ic
S1	0	00C2	**PWM**	OFF	OFF	**ON**	OFF	OFF	+ve	-ve	0
S2	1	0C02	**PWM**	OFF	OFF	OFF	OFF	**ON**	+ve	0	-ve
S3	2	0C20	OFF	OFF	**PWM**	OFF	OFF	**ON**	0	+ve	-ve
S4	3	002C	OFF	**ON**	**PWM**	OFF	OFF	OFF	-ve	+ve	0

Object Definition

The structure of CAPTURE object is defined by following structure definition for x280x series

```
typedef struct { int32 EventPeriod;      // Output: Timer value difference between two edges (Q0)
                 Uint16 CapReturn;       // Output: Status of one entry of first event of ECAP pin (Q0)
               } CAPTURE;
```

Item	Name	Description	Format	Range(Hex)
Inputs	CAPn	Capture input signals to 28x device	N/A	0-3.3 v
Outputs	EventPeriod (x280x)	Timer value difference between two edges detected.	0	80000000-7FFFFFFF
	CapReturn	Ecap first event status	0	0-1

Special Constants and Data types

CAPTURE

The module definition is created as a data type. This makes it convenient to instance an interface to the CAPTURE driver. To create multiple instances of the module simply declare variables of type CAPTURE.

CAPTURE_DEFAULTS

Structure symbolic constant to initialize CAPTURE module. This provides the initial values to the terminal variables as well as method pointers.

This default definition of the object implements two methods – the initialization and the runtime compute macro for CAPTURE generation. This is implemented by means of a macro pointer, and the initializer sets this to CAP_INIT_MACRO and CAP_MACRO macros for x280x. The argument to this macro is the address of the CAPTURE object.

Module Usage

Instantiation
The following example instances one CAPTURE object
CAPTURE cap1;

Initialization
To Instance pre-initialized objects
CAPTURE cap1 = CAPTURE_DEFAULTS;

Invoking the computation macro
CAP_INIT_MACRO (1); // For cap#1
CAP_MACRO (1,cap1);

Example
The following pseudo code provides the information about the module usage.

```
main()
{

        CAP_INIT_MACRO(1);              // Call init macro for cap1

}

void interrupt periodic_interrupt_isr()
{
   Uint16 CapReturn;
   Uint32 EventPeriod;

   CapReturn = CAP_MACRO(1,cap1);

   //  if status==1 then a time stamp was not read,
   //   if status==0 then a time stamp was read

   if(status==0)
   {
      EventPeriod=(int32)(cap1.EventPeriod);        // Read out new time stamp
   }

}
```

Description

This module stores the real-time values of four user selectable software Q15 variables in the data RAM provided on the 28xx DSP. Four variables are selected by configuring four module inputs, *iptr1, iptr2, iptr3* and *iptr4*, point to the address of the four variables. The starting addresses of the four RAM locations, where the data values are stored, are set to DLOG_4CH_buff1, DLOG_4CH_buff2, DLOG_4CH_buff3, and DLOG_4CH_buff4. The DATALOG buffer size, prescalar, and trigger value are also configurable.

Object Definition

The structure of DLOG_4CH object is defined by following structure definition

```
typedef struct {   long  task;         // Variable:  Task address pointer
                   int  *iptr1;        // Input: First input pointer (Q15)
                   int  *iptr2;        // Input: Second input pointer (Q15)
                   int  *iptr3;        // Input: Third input pointer (Q15)
                   int  *iptr4;        // Input: Fourth input pointer (Q15)
                   int  trig_value;    // Input: Trigger point (Q15)
                   int  prescalar;     // Parameter: Data log prescale
                   int  skip_cntr;     // Variable:  Data log skip counter
                   int  cntr;          // Variable:  Data log counter
                   long write_ptr;     // Variable:  Graph address pointer
                   int  size;          // Parameter: Maximum data buffer
                   int  (*init)();     // Pointer to init function
                   int  (*update)();   // Pointer to update function
                } DLOG_4CH;
```

Item	Name	Description	Format	Range(Hex)
Inputs	iptr1	Input pointer for the first Q15 variable	Q0	00000000-FFFFFFFF
	iptr2	Input pointer for the second Q15 variable	Q0	00000000-FFFFFFFF
	iptr3	Input pointer for the third Q15 variable	Q0	00000000-FFFFFFFF
	iptr4	Input pointer for the fourth Q15 variable	Q0	00000000-FFFFFFFF
Outputs	N/A	Data RAM	N/A	N/A
DATALOG Parameter	prescalar	Data log prescaler	Q0	0000-7FFF
	trig_value	Trigger point based on the fist Q15 variable	Q15	8000-7FFF
	size	Maximum data buffer	Q0	0000-7FFF
Internal	skip_cntr	Data log skip counter	Q0	0000-7FFF
	cntr	Data log counter	Q0	0000-7FFF
	write_ptr	Graph address pointer	Q0	00000000-FFFFFFFF
	task	Task address pointer	Q0	00000000-FFFFFFFF

Note: The trigger value is with reference to the input *iptr1. In accordance with this, the input connected to channel 1 should be time varying, and the trigger value should be set up such that input crosses the trigger value.

The other channels are captured synchronous to the channel 1. There is no trigger mechanism on channels 2 through 4.

Special Constants and Data types

DLOG_4CH
The module definition is created as a data type. This makes it convenient to instance an interface to the DATALOG driver. To create multiple instances of the module simply declare variables of type DLOG_4CH.

DLOG_4CH_handle
User defined Data type of pointer to DATALOG module

DLOG_4CH_DEFAULTS
Structure symbolic constant to initialize DATALOG module. This provides the initial values to the terminal variables as well as method pointers.

Methods

int DLOG_4CH_init(DLOG_4CH *);
int DLOG_4CH_update(DLOG_4CH *);

This default definition of the object implements two methods – the initialization and the runtime update function for DATALOG. This is implemented by means of a function pointer, and the initializer sets this to DLOG_4CH_init and DLOG_4CH_update functions for x281x/x280x. The argument to this function is the address of the DATALOG object.

Module Usage

Instantiation
The following example instances one DATALOG object
DLOG_4CH dlog1;

Initialization
To Instance pre-initialized objects
DLOG_4CH dlog1 = DLOG_4CH_DEFAULTS;

Invoking the computation function
dlog1.init(&dlog1);
dlog1.update(&dlog1);

Example

The following pseudo code provides the information about the module usage.

```
main()
{

        dlog1.iptr1 = &Q15_var1;        // Pass input to DATALOG module
        dlog1.iptr2 = &Q15_var2;        // Pass input to DATALOG module
        dlog1.iptr3 = &Q15_var3;        // Pass input to DATALOG module
        dlog1.iptr4 = &Q15_var4;        // Pass input to DATALOG module
        dlog1.trig_value = 0x0;         // Pass input to DATALOG module
        dlog1.size = 0x400;             // Pass input to DATALOG module
        dlog1.prescalar = 1;            // Pass input to DATALOG module
        dlog1.init(dlog1);              // Call init function for dlog1
}

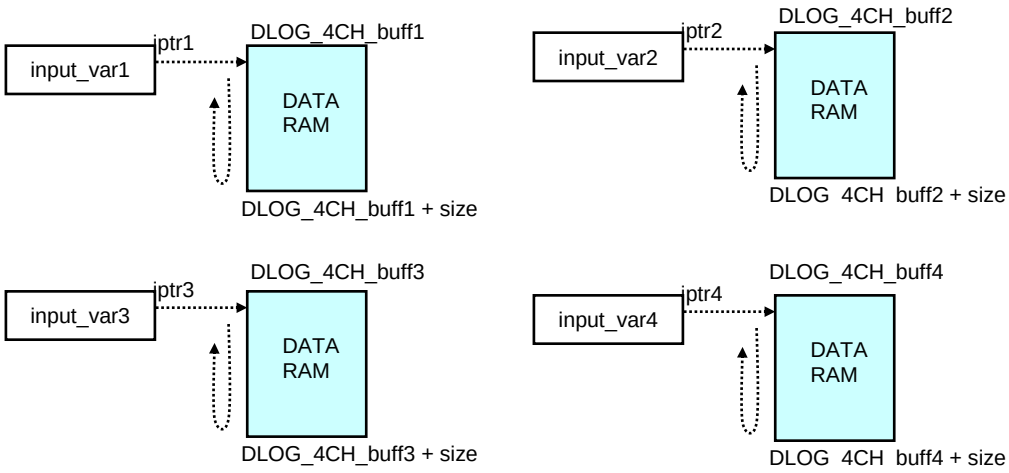
void interrupt periodic_interrupt_isr()
{

        dlog1.update(&dlog1);           // Call update function for dlog1

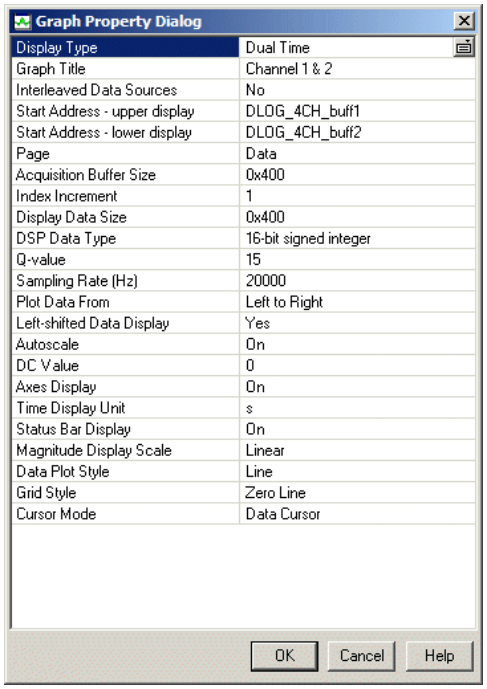
}
```

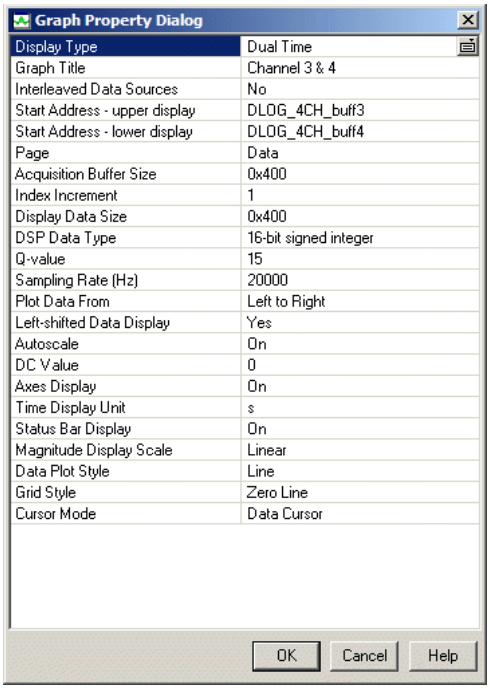
Technical Background

This software module stores up to four real-time Q15 values of each of the selected input variables in the data RAM as illustrated in the following figures. The starting addresses of four RAM sections, where the data values are stored, are set to DLOG_4CH_buff1, DLOG_4CH_buff2, DLOG_4CH_buff3, and DLOG_4CH_buff4.



To show four stored Q15 variables in CCS graphs properly, the properties of two dual time graphs for these variables should be configured as shown in the following figures. In the software, the default buffer size is 0x400. The sampling rate is usually same as ISR frequency. In this case, it is 20 kHz with the prescalar of 1.





Description

This module produces a commutation trigger for a 3-ph BLDC motor, based on hall signals received on GPIO pins 24, 25, and 26. Edges detected are validated or debounced, to eliminate false edges often occurring from motor oscillations. The software attempts all (6) possible commutation states to initiate motor movement. Once the motor starts moving, commutation occurs on each debounced edge from received hall signals.

Object Definition

The structure of HALL3 object is defined by following structure definition

```
typedef struct { Uint16 CmtnTrigHall;          // Output: Commutation trigger for Mod6cnt input
                 Uint16 CapCounter;            // Variable: Running cnt of detected edges on CAP/GPIO
                 Uint16 DebounceCount;         // Variable: Counter/debounce delay current value
                 Uint16 DebounceAmount;        // Parameter: Counter delay amount to
                                               //   validate/debounce GPIO readings
                 Uint16 HallGpio;              // Variable: Most recent logic level on CAP/GPIO
                 Uint16 HallGpioBuffer;        // Variable: Buffer of last logic level on CAP/GPIO while
                                               //       being debounced
                Uint16 HallGpioAccepted;       // Variable: Debounced logic level on CAP/GPIO
                Uint16 EdgeDebounced;          // Variable: Trigger from Debounce macro to Hall_Drv,
                                               //     if = 0x7FFF edge is debounced
                Uint16 HallMap[6];  // Variable: CAP/GPIO logic levels for HallMapPointer = 0-5
                Uint16 CapFlag;     // Variable: CAP flags, indicating which CAP/GPIO detected
                                    // the edge
                Uint16 StallCount;  // Variable: If motor stalls, this counter overflows triggers
                                    // commutation to start rotation. Rotation is defined as
                                    // an edge detection of a hall signal.
               Uint16 HallMapPointer; // Input/Output: During the map created, this variable points
                                      // to the current commutation state.  After map creation, it
                                      // points to the next commutation state.
              int16 Revolutions;  // Parameter: Running counter, with a revolution defined as 1-
                                  //  cycle of the 6 hall stateson
            } HALL3;
```

Item	Name	Description	Format	Range(Hex)
Inputs	CAP/GPIO	CAP/GPIO inputs (H/W)	N/A	0-3.3 v
	HallMapPointer	As an input, it is defined by MOD6_CNT	Q0	0 - 5
Outputs	CmtnTrigHall	Commutation trigger for Mod6cnt input	Q0	0 or 7FFF
	HallMapPointer	During hall map creation, this variable points to the current commutation state. After map creation, it points to the next commutation state.	Q0	0 - 5
HALL3 parameter	DebounceAmount	Counter delay amount to validate/debounce GPIO readings	Q0	0000-7FFF
	Revolutions	Running counter, with a revolution defined as 1-cycle of the 6 hall states	Q0	8000-7FFF
Internal	CapCounter	Running count of detected edges on CAP/GPIO	Q0	0000-7FFF
	DebounceCount	Counter/debounce delay current value	Q0	0000-7FFF
	HallGpio	Most recent logic level on CAP/GPIO	Q0	0000-0007
	HallGpioBuffer	Buffer of last logic level on CAP/GPIO while being debounced	Q0	0000-0007
	HallGpioAccepted	Debounced logic level on CAP/GPIO	Q0	0000-0007
	EdgeDebounced	Trigger from Debounce macro to Hall_Drv, if = 0x7FFF edge is debounced	Q0	0 or 7FFF
	HallMap[6]	CAP/GPIO logic levels for HallMapPointer = 0-5	Q0	0000-0007
	CapFlag	CAP flags, indicating which CAP/GPIO detected the edge	Q0	0000-0007
	StallCount	If motor stalls, this counter overflow triggers commutation to start rotation. Rotation is defined as an edge detection of a hall signal.	Q0	0000-FFFF

Special Constants and Data types

HALL3

The module definition is created as a data type. This makes it convenient to instance an interface to the HALL3 driver. To create multiple instances of the module simply declare variables of type HALL3.

HALL3_DEFAULTS

Structure symbolic constant to initialize HALL3 module. This provides the initial values to the terminal variables as well as method pointers.

This default definition of the object implements two methods – the initialization and the runtime compute macro for HALL3. This is implemented by means of a macro pointer, and the initializer sets this to HALL3_INIT_MACRO and HALL3_READ_MACRO macros for x280x. The argument to this macro is the address of the HALL3 object.

Module Usage

Instantiation
The following example instances one HALL3 object
HALL3 hall;

Initialization
To Instance pre-initialized objects
HALL3 hall = HALL3_DEFAULTS;

Invoking the computation macro
HALL3_INIT_MACRO (hall);
HALL3_READ_MACRO (hall);

Example

The following pseudo code provides the information about the module usage.

```
main()
{

        HALL3_INIT_MACRO (hall);          // Call init macro for hall3

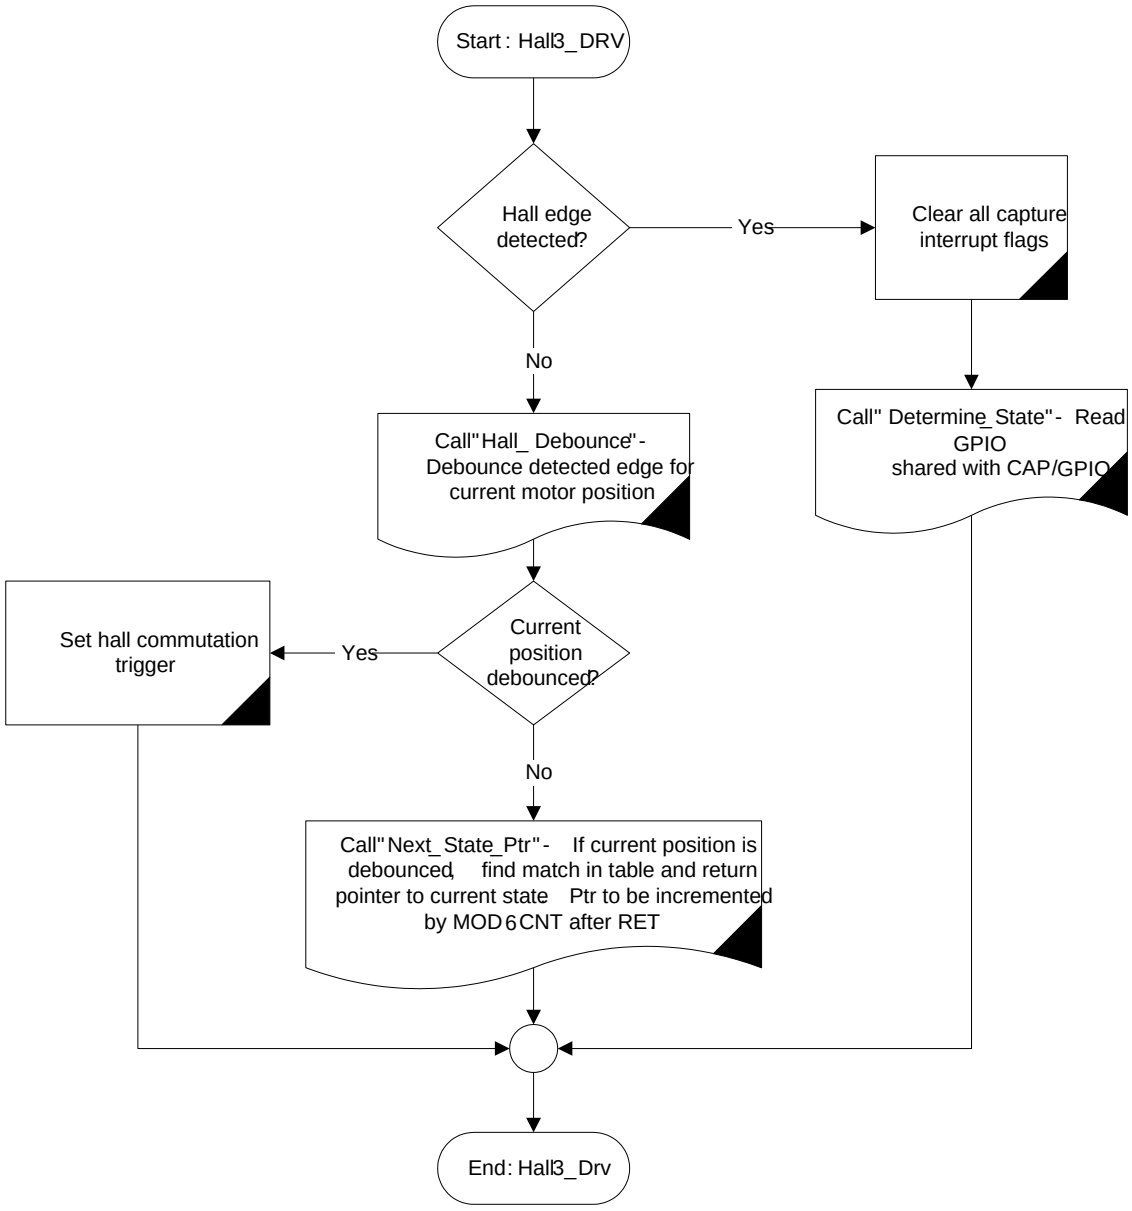
}

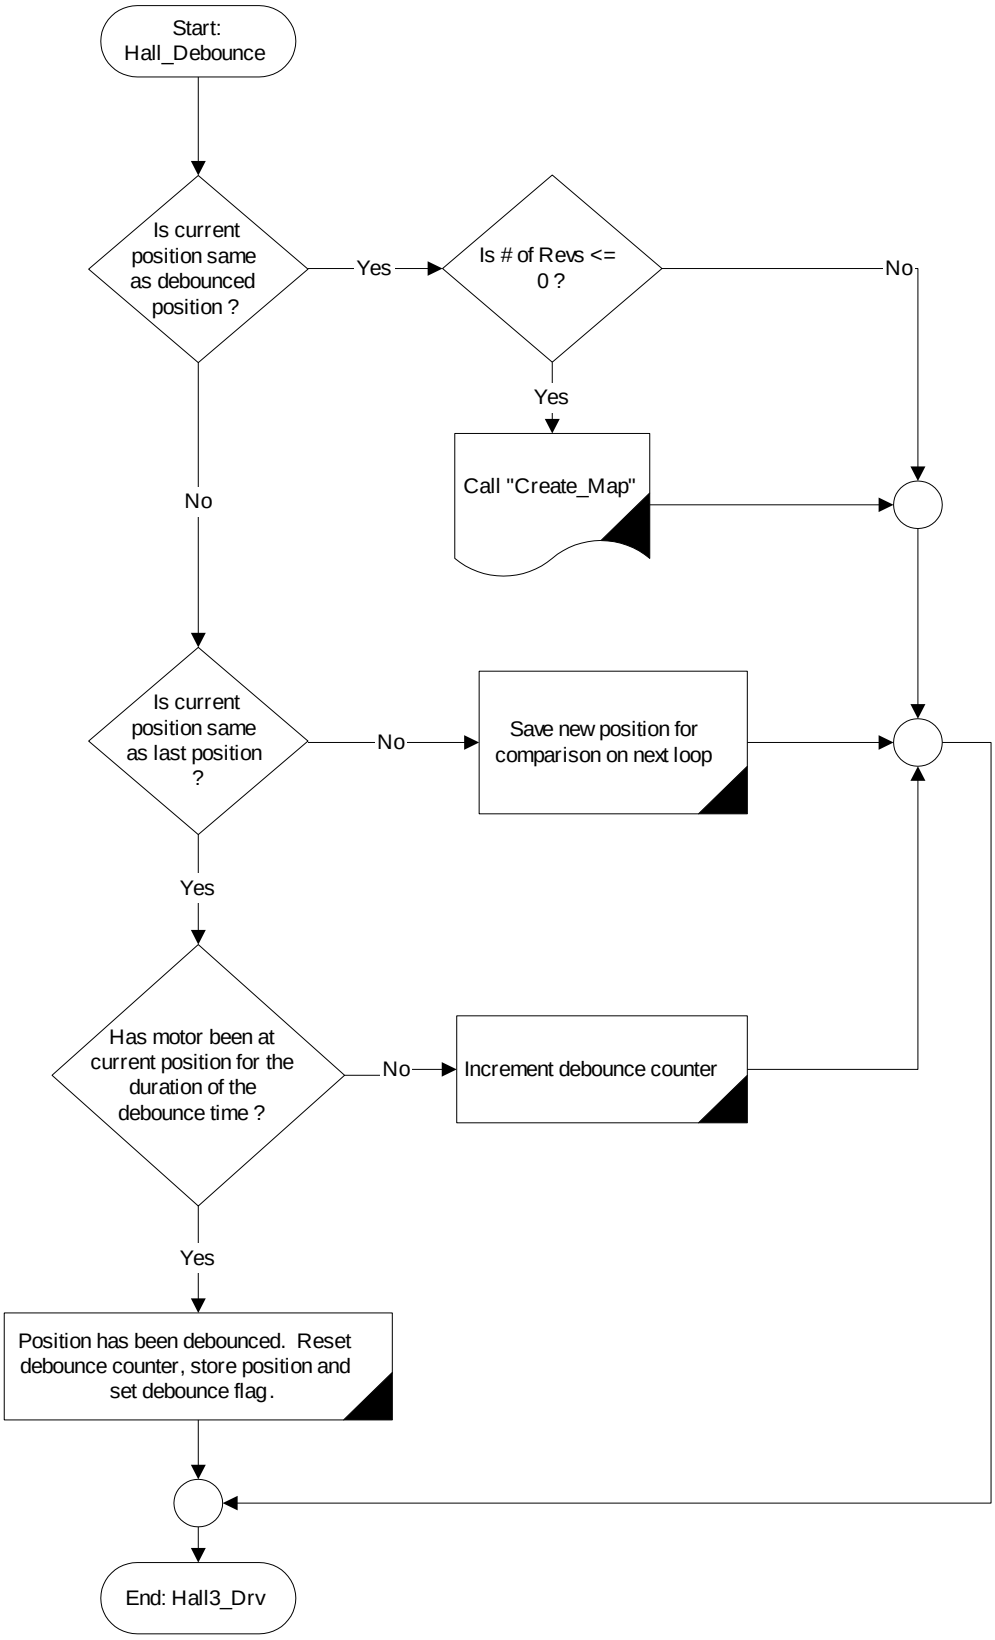
void interrupt periodic_interrupt_isr()
{

        HALL3_READ_MACRO (hall);    // Call the hall3 read macro

}
```

Software Flowcharts





Start: Hall_Debounce
Is current position same as debounced position ?
Yes
Is # of Revs <= 0 ?
No
Yes
Call "Create_Map"
No
Is current position same as last position ?
No
Save new position for comparison on next loop
Yes
Has motor been at current position for the duration of the debounce time ?
No
Increment debounce counter
Yes
Position has been debounced. Reset debounce counter, store position and set debounce flag.
End: Hall3_Drv

Determine_State
Set CAP/GPIO as GPIO Inputs
Read logic levels on GPIOs and save to memory (3-bits, right justified)
Reset CAP/GPIOs to use capture logic
End :
Determine_State

Description

This module converts any s/w variables into the PWM signals in EPWMxA/B for 280x. Thus, it can be used to view the signal, represented by the variable, at the outputs of the PWMxA, PWMxB, pins through the external low-pass filters.

Target Devices: 28x Fixed Point

IQmath library files for C: IQmathLib.h, IQmath.lib

C Version File Names: f2805xpwmdac.h (for x2805x)

C Interface

Object Definition

The structure of PWMDAC object is defined by following structure definition

```
typedef struct {
  _iq MfuncC1;          // Input: PWM 1 Duty cycle ratio (Q24)
  _iq MfuncC2;          // Input: PWM 2 Duty cycle ratio (Q24)
Uint16 PeriodMax;       //  Parameter: PWMDAC half period in number of clocks  (Q0)
Uint16 HalfPerMax;      // Parameter: Half of PeriodMax
} PWMDAC;
```

Item	Name	Description	Format	Range(Hex)
Inputs	MfuncCx	PWM duty cycle ratio	Q24	$(-2^{24},2^{24})$
Outputs	PWMxA/B	Output signals from the PWMxA/B pins	N/A	0-3.3 V
PWMDAC parameter	PeriodMax	PWMDAC half period in number of clocks	Q0	8000-7FFF
	HalfPerMax	Half of PeriodMax	Q0	8000-7FFF

Special Constants and Data types

PWMDAC

The module definition is created as a data type. This makes it convenient to instance an interface to the PWMDAC driver. To create multiple instances of the module simply declare variables of type PWMDAC.

PWMDAC_DEFAULTS

Structure symbolic constant to initialize PWMDAC module. This provides the initial values to the terminal variables as well as method pointers.

This default definition of the object implements two methods – the initialization and the runtime compute macro for PWMDAC generation. This is implemented by means of a macro pointer, and the initializer sets this to PWMDAC_INIT_MACRO and PWMDAC_MACRO macros for x280x. The argument to this macro is the address of the PWMDAC object.

Module Usage

Instantiation

The following example instances one PWMDAC object

```
PWMDAC  pwmdac1;
```

Initialization

To Instance pre-initialized objects

```
PWMDAC pwmdac1 = PWMDAC_DEFAULTS;
```

Invoking the computation macro

```
PWMDAC_INIT_MACRO(pwmdac1);
PWMDAC_MACRO(pwmdac1);
```

Example

The following pseudo code provides the information about the module usage.

```
main()
{
  pwmdac1.PeriodMax=500;                    // @60Mhz clock freq, PWM freq = 60kHz
  PWMDAC_INIT_MACRO (6, pwmdac1)            // PWM 6A,6B
}

void interrupt periodic_interrupt_isr()
{
   pwmdac1.MfuncC1 = variable1;     // variable1 is in GLOBAL_Q
   pwmdac1.MfuncC2 = variable2;     // variable2 is in GLOBAL_Q
   PWMDAC_MACRO (6,pwmdac1)  // update macro for pwmdac1 for PWM ch #6
}
```

Technical Background

The external low-pass filters are necessary to view the actual signal waveforms as seen in Figure 1. The (1st-order) RC low-pass filter can be simply used for filter out the high frequency component embedded in the actual low frequency signals. To select R and C values, its time constant can be expressed in term of cut-off frequency (f_c) as follow:

$$\tau = RC = \frac{1}{2\pi f_c} \quad (1)$$

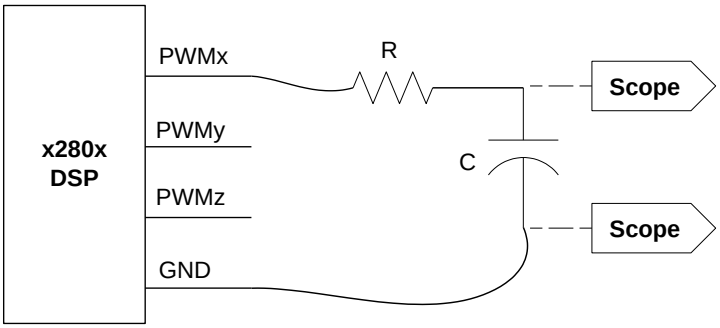

Figure 1: External RC low-lass filter connecting to PWMx pin in x280x DSP

Description

This module uses the duty ratio information and calculates the compare values for generating PWM outputs. The compare values are used in the full compare EPWM unit in 280x. This also allows PWM period modulation.

Object Definition

The structure of PWMGEN object is defined by following structure definition

```
typedef struct {  Uint16 PeriodMax;     // Parameter: PWM Half-Period in CPU clock cycles (Q0)
                  Uint16 HalfPerMax;    // Parameter: Half of PeriodMax (Q0)
                  Uint16 Deadband;      // Parameter: PWM deadband in CPU clock cycles (Q0)
                  _iq MfuncC1;          // Input: PWM 1 Duty cycle ratio (Q24)
                  _iq MfuncC2;          // Input: PWM 2 Duty cycle ratio (Q24)
                  _iq MfuncC3;          // Input: PWM 3 Duty cycle ratio (Q24)
               } PWMGEN;
```

Item	Name	Description	Format	Range(Hex)
Inputs	MfuncCx	PWM duty cycle ratio	Q24	$(-2^{24},2^{24})$
Outputs	PWMx	Output signals from the 6 PWM pins	N/A	0-3.3 V
PWMGEN parameter	PeriodMax	PWM Half-Period in CPU clock cycles	Q0	8000-7FFF
	HalfPerMax	Half of PeriodMax	Q0	8000-7FFF
	Deadband	PWM deadband in CPU clock cycles	Q0	8000-7FFF

Special Constants and Data types

PWMGEN

The module definition is created as a data type. This makes it convenient to instance an interface to the PWMGEN driver. To create multiple instances of the module simply declare variables of type PWMGEN.

PWMGEN_DEFAULTS

Structure symbolic constant to initialize PWMGEN module. This provides the initial values to the terminal variables as well as method pointers.

This default definition of the object implements two methods – the initialization and the runtime compute macro for PWMGEN generation. This is implemented by means of a pointer, and the initializer sets this to PWM_INIT_MACRO and PWM_MACRO macros for x280x. The argument to this macro is the address of the PWMGEN object.

Module Usage

Instantiation
The following example instances one PWMGEN object
PWMGEN pwm1;

Initialization
To Instance pre-initialized object
PWMGEN pwm1 = PWMGEN_DEFAULTS;

Invoking the computation macro
PWM_INIT_MACRO (pwm1);
PWM_MACRO (pwm1);

Example

The following pseudo code provides the information about the module usage.

```
main()
{

   pwm1.PeriodMax = 3000;       // PWM frequency = 10 kHz, clock = 60 MHz
   pwm1.HalfPerMax = pwm1.PeriodMax/2;
   PWM_INIT_MACRO (pwm1); // Call init macro for pwm1

}

void interrupt periodic_interrupt_isr()
{

        pwm1.MfuncC1 = svgen_dq1.Ta;    // svgen_dq1.Ta is in GLOBAL_Q
        pwm1.MfuncC2 = svgen_dq1.Tb;    // svgen_dq1.Tb is in GLOBAL_Q
        pwm1.MfuncC3 = svgen_dq1.Tc;    // svgen_dq1.Tc is in GLOBAL_Q
        PWM_MACRO (1,2,3,pwm1);         // Call update macro for pwm1 for PWM ch #1,2,3

}
```

Description

This module determines the rotor position and generates a direction (of rotation) signal from the shaft position encoder pulses.

Object Definition

The structure of QEP object is defined by following structure definition

```
typedef struct { int32 ElecTheta;          // Output: Motor Electrical angle (Q24)
                 int32 MechTheta;          // Output: Motor Mechanical Angle (Q24)
                 Uint16 DirectionQep;      // Output: Motor rotation direction (Q0)
                 Uint16 QepPeriod;         // Output: Capture period of QEP signal (Q0)
                 Uint32 QepCountIndex;     // Variable: Encoder counter index (Q0)
                 int32 RawTheta;           // Variable: Raw angle from EQEP position counter (Q0)
                 Uint32 MechScaler;        // Parameter: 0.9999/total count  (Q30)
                 Uint16 LineEncoder;       // Parameter: Number of line encoder (Q0)
                 Uint16 PolePairs;         // Parameter: Number of pole pairs (Q0)
                 int32 CalibratedAngle;    // Parameter: Raw offset between encoder and ph-a (Q0)
                 Uint16 IndexSyncFlag;     // Output: Index sync status (Q0)
               }  QEP;
```

Item	Name	Description	Format	Range(Hex)
Inputs	QEP_A	QEP_A signal applied to QEP1-A	N/A	0-3.3 v
	QEP_B	QEP_A signal applied to QEP1-B	N/A	0-3.3 v
	QEP_Index	QEP_Index signal applied to QEP1-I	N/A	0-3.3 v
Outputs	ElecTheta	Motor Electrical angle	Q15 (281x) Q24 (280x)	0000-7FFF 00000000-7FFFFFFF (0 – 360 degree)
	MechTheta	Motor Mechanical Angle	Q15 (281x) Q24 (280x)	0000-7FFF 00000000-7FFFFFFF (0 – 360 degree)
	DirectionQep	Motor rotation direction	Q0	0 or 1
	IndexSyncFlag	Index sync status	Q0	0 or F0
QEP parameter	MechScaler*	MechScaler = 1/total count, total count = 4*no_lines_encoder	Q30	00000000-7FFFFFFF
	PolePairs	Number of pole pairs	Q0	1,2,3,…
	CalibratedAngle	Raw offset between encoder and phase a	Q0	8000-7FFF
Internal	QepCountIndex	Encoder counter index	Q0	8000-7FFF
	RawTheta	Raw angle from Timer 2	Q0	8000-7FFF

*MechScaler in Q30 is defined by a 32-bit word-length

Special Constants and Data types

QEP
The module definition is created as a data type. This makes it convenient to instance an interface to the QEP driver. To create multiple instances of the module simply declare variables of type QEP.

QEP_DEFAULTS
Structure symbolic constant to initialize QEP module. This provides the initial values to the terminal variables as well as method pointers.

This default definition of the object implements three methods – the initialization, the runtime compute, and interrupt macros for QEP generation. This is implemented by means of a macro pointer, and the initializer sets this to QEP_INIT_MACRO, and QEP_MACRO macros for x280x. The argument to this macro is the address of the QEP object.

Module Usage

Instantiation
The following example instances one QEP object
QEP qep1;

Initialization
To Instance pre-initialized objects
QEP qep1 = QEP_DEFAULTS;

Invoking the computation macro
QEP_INIT_MACRO (1, qep1);
QEP_MACRO (1, qep1);

The index event handler resets the QEP counter, and synchronizes the software/hardware counters to the index pulse. Also it sets the QEP IndexSyncFlag variable to reflect that an index sync has occurred.

The index handler is invoked in an interrupt service routine. Of course the system framework must ensure that the index signal is connected to the correct pin and the appropriate interrupt is enabled and so on.

Example

The following pseudo code provides the information about the module usage.

```
main()
{
        QEP_INIT_MACRO(1,qep1);          // Call init macro for qep1
}

void interrupt periodic_interrupt_isr()
{
        QEP_MACRO(1,qep1);          // Call compute macro for qep1
}
```

Technical Background

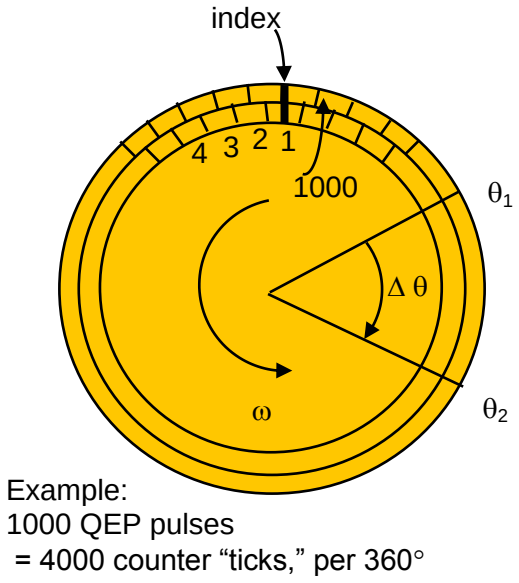

Figure 1. Speed sensor disk

Figure 1 shows a typical speed sensor disk mounted on a motor shaft for motor speed, position and direction sensing applications. When the motor rotates, the sensor generates two quadrature pulses and one index pulse. These signals are shown in Figure 2 as QEP_A, QEP_B and QEP_index.

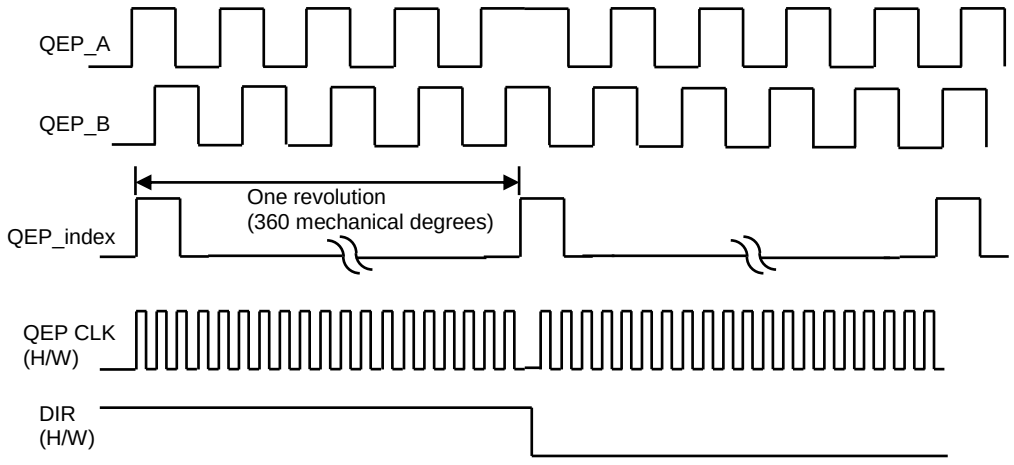

Figure 2. Quadrature encoder pulses, decoded timer clock and direction signal.

For the x280x devices, QEP_A and QEP_B signals are applied to the EQEP1A and EQEP1B pins, respectively. The QEP_index signal is applied to the EQEP1I pin. And the position counter is obtained by QPOSCNT register.

Now the number of pulses generated by the speed sensor is proportional to the angular displacement of the motor shaft. In Figure 1, a complete 360° rotation of motor shaft generates 1000 pulses of each of the signals QEP_A and QEP_B. The QEP circuit in 281x counts both edges of the two QEP pulses. Therefore, the frequency of the counter clock, QEP_CLK, is four times that of each input sequence. This means, for 1000 pulses for each of QEP_A and QEP_B, the number of counter clock cycles will be 4000. Since the counter value is proportional to the number of QEP pulses, therefore, it is also proportional to the angular displacement of the motor shaft.

For the x280x devices, the QDF bit in QEOSTS register is used to check the rotational direction. The index pulse resets the timer counter T2CNT and sets the index synchronization flag *IndexSyncFlag* to 00F0. Thus the counter T2CNT gets reset and starts counting the QEP_CLK pulses every time a QEP_index high pulse is generated.

To determine the rotor position at any instant of time, the counter value(T2CNT) is read and saved in the variable *RawTheta.* This value indicates the clock pulse count at that instant of time. Therefore, *RawTheta* is a measure of the rotor mechanical displacement in terms of the number of clock pulses. From this value of *RawTheta*, the corresponding per unit mechanical displacement of the rotor, *MechTheta*, is calculated as follows:

Since the maximum number of clock pulses in one revolution is 4000, i.e., maximum count value is 4000, then a coefficient, *MechScaler*, can be defined as,

$$MechScaler \times 4000 = 360^0\, mechanical = 1\, per\ unit\,(pu)\, mechanical\ displacement$$
$$\Rightarrow MechScaler = (1/4000)\, pu\ mech\ displacement / count$$
$$= 16777\, pu\ mech\ displacement / count\,(in\ Q30)$$

Then, the pu mechanical displacement, for a count value of *RawTheta*, is given by,

$$MechTheta = MechScaler \times RawTheta$$

If the number of pole pair is *polepairs*, then the pu electrical displacement is given by,

$$ElecTheta = PolePairs \times MechTheta$$

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof.
